(54) Title: VEHICLE POWERED BY A FUEL CELL/GAS TURBINE COMBINATION

(57) Abstract

A hybrid electric vehicle (10) powered by a combination fuel cell (22) and a gas turbine (26) driven generator (24). The fuel cell (22) is sized relative to the gas turbine (26) and the vehicle (10) such that up to about 50 percent of the vehicle's maximum sustainable power is supplied by the fuel cell (22) electrical power output. This relative power source size achieves improved fuel consumption compared to vehicles powered by combustion engines without the cost penalty associated with a fuel cell large enough to power the vehicle. At low power requirements, the fuel cell (22) efficiently provides all or most of the vehicle's (10) power requirements. As the power requirements increase, additional fuel is burned in the gas turbine (26).

VEHICLE POWERED BY A FUEL CELL/GAS TURBINE COMBINATION

TECHNICAL FIELD

5 The present invention relates to a hybrid electric vehicle having a combination fuel cell and a gas turbine power generator and in particular, to a hybrid electrical vehicle having a combination fuel cell and a gas turbine power generator wherein the majority of the power to propel the vehicle under steady-state urban driving conditions is derived from the fuel cell.

BACKGROUND ART

10 The most popular power source for automotive applications is an internal combustion engine connected to a mechanical drive train which in turn rotates at least one wheel to drive the automobile. However, state and federal automotive emission laws are becoming increasingly more difficult to meet using current internal combustion engines powered by hydrocarbon fuels which emit
15 large quantities of carbon dioxide, carbon monoxide, and various nitrogen oxides as by-products. Additionally, even the most efficient internal combustion engines are not very efficient, having a maximum efficiency of approximately 35% or less. The efficiency of an internal combustion engine increases as the energy output increases. During urban driving cycles where the required power output
20 is the lowest, the efficiency is even lower.

 As an alternative, electric vehicles were developed with the electric energy stored in large battery packs that replace the internal combustion engine and powered the automobile. The stored energy drives at least one electric motor which in turn rotates at least one drive wheel. However, there are still many
25 drawbacks with the expensive battery packs such as long recharge periods, minimal driving distances before recharging, lack of power for passing and climbing hills, and excessively large and heavy battery packs.

 Hybrid vehicles have been designed wherein for example, the automobile is continuously powered by a relatively low-powered, fuel-burning

power source such as turbogenerator which can be run near or at peak efficiency. When extra power is required, for example, during acceleration or hill climbing, the surge power is provided by a storage device which stores energy during steady state driving conditions such as driving at a constant speed on a level road.

5 Prior art storage devices include flywheels, pressurized fluid accumulators, batteries, and capacitors. The fundamental problem with these systems is that maximum efficiency is still limited by the fuel burning combustion engine whether it be internal combustion, spark ignited, diesel or a gas turbine.

A relatively new technology proposed for powering automobiles is the use of fuel cells to provide electric power. A fuel cell creates electricity through a chemical reaction wherein a hydrocarbon fuel oxidizes and forms carbon dioxide and water as by-products. Fuel cells have an efficiency of approximately 70-80%, much more efficient than internal combustion engines at the relatively low power requirements of urban driving. However, for a fuel cell to provide all the necessary power to an automobile to climb hills, drive at highway speeds, and supply passing power, the fuel cell would be too large, expensive, and heavy for an automobile. See for example ASME 97-GT-340, Parametric Study of Fuel Cell and Gas Turbine Combined Cycle Performance by Stephenson, Dawn and Ritchey, Ian.

20

DISCLOSURE OF INVENTION

The present invention solves the above-mentioned problems and provides a clean-burning, efficient, economical, automotive power source by converting a substantial portion of the fuel consumed by the vehicle directly to electrical energy using a fuel cell at very efficient conversion rates without the prohibitive cost of the existing fuel cell vehicle. At higher power requirements, a gas turbine generates additional power.

Accordingly, a hybrid electric vehicle is provided with an electric motor drivingly connected to a at least one driven wheel. The vehicle has a source of hydrocarbon fuel, a fuel cell for converting the hydrocarbon fuel and oxygen contained in air directly to electric energy and fuel cell exhaust gas, and a gas turbine engine powered by fuel cell exhaust gas as well as by directly

30

burning hydrocarbon fuel. An electric generator is coupled to the gas turbine to provide electrical energy which in conjunction with the electrical output of the fuel cell powers the vehicle's electric motor. A power controller responsive to a demand signal from a vehicle occupant regulates the operation of the fuel cell and the gas turbine to cause the fuel cell and the fuel cell exhaust gases to provide vehicle power when the vehicle's need are generally below the maximum fuel cell power output level, and to provide hydrocarbon fuel to the gas turbine to generate additional power as required up to a maximum sustainable power level. The fuel cell and the gas turbine are sized relative to the vehicle such that the maximum electrical power output of the fuel cell is no greater than about 50% and, preferably, no greater than about 25%, of the maximum sustainable power level.

BRIEF DESCRIPTION OF DRAWINGS

BEST MODE FOR CARRYING OUT THE INVENTION

5 Figure 1 schematically illustrates a hybrid electric vehicle 10 of the present invention. Hybrid electric vehicle 10 has a body 12, a pair of front wheels 14 and 14', and a pair of rear wheels 16 and 16'. At least one of the wheels is drivingly connected to an electric motor 18, 18'. In the disclosed embodiment rear wheels 16 and 16' are connected to electric motors 18 and 18' and by the drive train 20 and 20' as shown. Alternatively, front wheels 14 can be driven individually or in combination with driven rear wheels 16 and 16'. The hybrid electric vehicle 10 is driven by providing electrical power to electric motors 18 and 18' supplied by two sources - fuel cell 22 and electric generator 24 which is driven by gas turbine 26. The fuel source 28, such as in gasoline tank or alternatively a propane tank (not shown), stores hydrocarbon fuel, such as gasoline or other hydrocarbon fuel, to be supplied to the fuel cell 22 and gas turbine 26.

15 A power controller 30 is responsive to a control or "demand" signal, such as acceleration/brake signals 9 generated by a vehicle operator 19, to regulate the electric motors 18 and 18'. The power controller 30 controls the motor torque by regulating a delivery of hydrocarbon fuel and air to both the fuel cell 22 and the gas turbine 26. In low-load conditions, where the energy needed is less than the maximum electrical power output of the fuel cell 22, the power controller 30 causes the electricity needed by the motor to be generated by the fuel cell and by the gas turbine utilizing fuel cell exhaust gases. When the vehicle's power requirements exceed the output capacity of the fuel cell, the power controller causes additional hydrocarbon fuel and compressed air to be supplied to the gas turbine to generate additional power as needed by the vehicle up to a maximum sustainable power level.

30 In practicing the present invention, overall fuel economy is a trade-off of overall efficiency and system costs. Maximum overall fuel efficiency is

achieved with a large fuel cell and a relatively small gas turbine which is capable of recovering energy from the fuel cell exhaust. A fuel cell/gas turbine combination of this type, which does not directly burn hydrocarbon fuel in the gas turbine, is efficient, although prohibitively expensive.

5 The present invention addresses this problem by sizing the fuel cell smaller than the gas turbine so that during most ordinary urban drive, the majority of the fuel will be consumed in the fuel cell. System cost will be controlled by keeping the fuel cell small and providing additional power as needed for acceleration, hill climbs, and sustained high speed cruising by burning
10 additional hydrocarbon fuel directly in the gas turbine engine.

 Ideally, for the present vehicle conditions, the fuel cell's power output and size is relative to the gas turbine and the vehicle, such that up to about 50 percent of the maximum sustainable power of the vehicle is supplied by the electric power output of the fuel cell. Preferably, up to about 25 percent of the
15 vehicle's power at the maximum sustainable power level is supplied by the electric power output of the fuel cell. And, in the embodiment illustrated in the drawings, about 10 percent of the vehicle's maximum sustainable power is supplied by the electric power output of the fuel cell depending on the particular vehicle weight, function, and other factors.

20 Figure 2 is a schematic illustration showing the interrelationship between the fuel cell 22 and the various components which make up the gas turbine. In the present embodiment in which the hydrocarbon fuel source 28 is a holding tank for gasoline, reformer 32 is provided between the source of hydrocarbon fuel and the fuel cell 22 in order to partially oxidize the gasoline in
25 a rich environment. The output of the reformer constitutes hot gases in which the hydrocarbons making up gasoline are broken down into free hydrogen, carbon monoxide, carbon dioxide and water.

 Fuel cell 22 is provided with two inputs. Fuel input 34 is connected to reformer 22 in order to receive partially oxidized hydrocarbon fuel
30 from hydrocarbon fuel source 28. Air inlet 36 supplies compressed preheated air to the fuel cell 22. Fuel cell 22 has an outlet at 38 for fuel cell exhaust gases and an electrical power outlet terminal 40 which provides electrical power to drive motors 18 and 18' via controller 30 (shown in Figure 1). Fuel pumps (not

shown) help pump the fuel from the fuel source 28 to fuel cell 22 and gas turbine 26 (shown in Figure 1).

5 In an embodiment, a solid oxide fuel cell (SOFC) or molten carbonate fuel cell (MCFC) is used, although other fuel cells will provide satisfactory results. In solid-oxide and molten-carbonate fuel cells, the arrangement of electrodes, electrolyte, and bipolar separator has orthogonal fuel and air passages in a generally planar arrangement. This planar geometry readily lends itself to a series connection of approximately 70 cells needed to provide a loaded terminal voltage of 50 volts, which is desirable for the power controller
10 30. The solid-oxide fuel cells preferably operate at an outlet temperature of approximately 850° C and at an operating pressure of three to five atmospheres, i.e., within the preferred range of the recuperating gas turbine 26. The molten-carbonate fuel cells preferably operate at an outlet temperature of approximately 650°C and at an operating pressure of perhaps three to five atmospheres, again,
15 an preferred operating range of the recuperating gas turbine 26. Applicants incorporate by reference an unpublished article by Professor Aldo Vieira da Rosa of Stanford University for its description of "SOFC" and "MCFC" fuel cells.

Gas turbine engine 26 (shown in Figure 1) has a compressor turbine 42 and a drive turbine 44 mounted on a common rotary shaft 46. The gas
20 turbine 26 is provided with a housing 48, as seen in Figure 3, which defines a compressor chamber 50, generally surrounding compressor turbine 42, and a drive turbine chamber 52, generally surrounding drive turbine 44. A series of combustors 54, 56, and 58 are circumferentially oriented about housing 48 for providing hot, compressed combustion products to the drive turbine chamber 52.
25 The hot exhaust gases from the fuel cell exhaust outlet 38 are provided to the drive turbine chamber 52 via an inlet formed in combustor 54 as best illustrated in Figure 5. Drive turbine 44 can be powered by fuel cell exhaust gases alone or a combination of fuel cell exhaust gases and the products of combustion generated by burning of fuel directly in combustors 54, 56 and 58.

30 In the embodiment illustrated in Figures 2-5, gas turbine engine 26 is provided with a internal recuperator 60 which utilizes waste heat from the drive turbine exhaust to preheat the compressed air output from compressor turbine 42. The preheated compressed air from the recuperator 60 is provided to

combustors 54, 56 and 58 as well as the air inlet 36 of fuel cell 22. Air valve 62 controls the flow of air from recuperator 60 to fuel cell 22. Air valves 64, 66, and 68 control the flow of air from recuperator 60 to combustors 54, 56 and 58 respectively. In like fashion, fuel valve 70 controls the flow of fuel to the fuel cell 22 via the reformer 32 while fuel valves 72, 74 and 76 respectively control the flow of fuel to combustors 54, 56 and 58. All the air valves and the fuel valves are controlled by controller 30 in order to precisely meter fuel and air in order to achieve the proper air/fuel balance, appropriate power output and turbine exhaust gas emissions.

Applicants hereby incorporate by reference SAE Paper No. 970292 entitled "The Capstone Turbogenerator as an Alternate Power Source," by Paul Craig, and SAE Paper No. 940510 entitled "Development of a 24 kW Gas Turbine-Driven Generator Set for Hybrid Vehicles."

As illustrated in Figure 3, electric generator 24 is directly mounted and coaxially aligned with gas turbine engine 24 and operatively connected to the gas turbine engine rotary shaft 46. The electric generator 24 provides electric power output which in combination with the fuel cell power output provides energy to drive motors 18 and 18'. One orientation of the combustors 54, 56 and 58 relative to the gas turbine housing are shown in Figures 4 and 5; however, it should be appreciated that alternative embodiments having more or fewer combustors will work. However the three combustors illustrated are expected to provide good performance through a wide range of operating conditions.

Figure 6 illustrates the relative power output from the fuel cell and a gas turbine at various operating conditions. The fuel cell in this particular application has a maximum electrical output of 5 kilowatts. In addition to this electrical output, the hot exhaust air from the fuel cell can provide additional 1.8 kilowatts of energy when this energy is recovered by the gas turbine by combusting the exhaust gases. Therefore, when less than 6.8 kilowatts of power is needed, all the energy can be derived from fuel supplied to the fuel cell.

When more energy is needed, the controller 30 supplies air and fuel to at least one of the combustors 54, 56 or 58. Fuel and air are proportionally supplied to the combustors in order to achieve the desired and necessary power level to operate the vehicle. At the maximum sustainable power

output indicated at 100 percent in Figure 6, the combination of fuel cell and the gas turbine driven generator will provide 50 kilowatts of power, 5 kilowatts delivered directly by the fuel cell and 45 kilowatts of power derived from the gas turbine, 1.8 kilowatts of the gas turbine's power is from fuel cell exhaust and
5 43.2 kilowatts of power is generated from the direct combustion of hydrocarbon fuel in the gas turbine. For different applications, the maximum output of the fuel cell and the turbine may vary. Figure 6 merely illustrates one possible combination for this particular vehicle.

When sizing the gas turbine and fuel cell for a particular vehicle,
10 it is important to appropriately size the gas turbine and fuel cell for the vehicle's torque requirement as dictated by the vehicle's weight, intended use, and desired performance. Figure 7 illustrates the power needed for the typical, relatively small hybrid electric vehicle equipped with a regenerative energy storage system such as a flywheel 80 as shown in Figure 1. A regenerative energy storage
15 system such as flywheel 80 will store energy during vehicle braking as well as storing energy during times of low power consumption.

In the alternative, battery 82 may be charged using electro-mechanical means during breaking and/or low power requirements and provide surge power. The hybrid vehicle will utilize the energy stored in the flywheel
20 during high load or acceleration maneuvers thereby limiting the power requirements of the fuel cell and gas turbine combination. The plot of power required during the urban dynamometer driving cycle for a representative hybrid vehicle shown in Figure 7 illustrates the power requirements appropriately decreased during the high-load portions of the test schedule resulting from the
25 dissipation of the flywheel energy.

Analyzing the load requirements of the vehicle during the Urban Dynamometer Driving Schedule as shown in Figure 7 highlights the fact that much of the Urban Dynamometer Driving Schedule is at very low power levels. The chart in Figure 8 is a histogram in which percentage of time spent at various
30 power levels is normalized by power output to effectively illustrate how much fuel is used at the various power levels.

The particular vehicle shown in this example has an average power consumption of approximately 5 kilowatts even though as apparent from the plot

in Figure 7 the time weighted averaged as even lower. The fuel cell is sized in this particular embodiment so that the electrical power output of the fuel cell is approximately equal to the average power consumption level during the Urban Dynamometer Driving Schedule. Considering that an additional 1.8 kilowatts of power is generated the gas turbine from fuel cell exhaust gases, a majority of the fuel needed by the vehicle during the Urban Dynamometer Driving Schedule will be from the fuel supplied to the fuel cell.

The fuel cell operates at a very high efficiency converting as much as 70 percent of the energy of hydrocarbon fuel into electrical energy when combined with a turbine for recovering energy from a fuel cell exhaust gas chamber. The present invention, however, achieves much of the efficiencies of a fuel cell without the prohibitive costs by sizing the fuel cell relatively small compared to the total vehicle energy needs. As illustrated in Figure 9, the combination of a solid oxide fuel cell of the type contemplated in the present invention in conjunction with a gas turbine provides both the high power output at a relatively low cost while maintaining excellent fuel efficiency during the low power output levels where urban commuter vehicles generally operate. The present invention therefore maintains a very good cost per maximum kilowatt output while having a very high efficiency at normal urban operating conditions.

Figure 10 illustrates the percentage of total output for the gas turbine, the fuel cell, and the recovered fuel cell exhaust at different levels of total power output for this one particular arrangement. At power requirements under 5 kilowatts, nearly all the generated power is obtained from the fuel cell with a small percentage coming from recovering the fuel cell exhaust gases. As the power requirement increases to approximately 5 kilowatts, the gas turbine begins contributing to the percent of the total power and approaches an approximate contribution of 90% at maximum sustainable power. The remainder of the power output is derived from the fuel cell and recovered fuel cell exhaust gases.

The vehicle according to the present invention will have the fuel cell sized relative to the gas turbine so when the vehicle is operating at the average power level required by the vehicle during the Urban Dynamometer Driving Schedule over about 50 percent of the vehicle's power needs are supplied

by the electrical power output of the fuel cell. Preferably, over about 60 percent of the vehicle's power needs will be supplied by the electrical power output of the fuel cell when a vehicle is operating at average power level occurring during the Urban Dynamometer Driving Schedule, and most preferably, as shown with
5 reference to the present illustrated embodiment, two-thirds of the vehicle's power needs will be provided by the electrical output of the fuel cell when operating at the average power level occurring during the urban dynamometer driving schedule. The balance of the power being supplied by the gas turbine recovering waste heat from the fuel cell exhaust.

10 While embodiments of the invention have been illustrated and described, it is not intended that these embodiments illustrate and describe all possible forms of the invention. Rather, the words used in the specification are words of description rather than limitation, and various changes may be made without departing from the spirit and scope of the invention.

WHAT IS CLAIMED IS:

1. A hybrid electric vehicle having at least one electric motor drivingly connected to at least one driven wheel, the hybrid electric vehicle comprising:

5 a source of hydrocarbon fuel;

a fuel cell for converting hydrocarbon fuel and oxygen contained in air into electrical energy, the fuel cell having a hydrocarbon fuel inlet, a compressed air inlet, an outlet for fuel cell exhaust gas, and an electrical power output;

10 a gas turbine engine having a compressor turbine and a drive turbine mounted on a rotary shaft, a housing defining a compressor chamber and a drive turbine chamber, at least one combustor for burning hydrocarbon fuel in combination with compressed air supplied by the compressor turbine to form hot compressed combustion products which are communicated to the drive turbine chamber, and an inlet for fuel cell exhaust gases in communication with the drive turbine chamber, the drive turbine being powered by fuel cell exhaust gases alone or in combination with combustion products resulting from the burning of hydrocarbon fuel in the combustor;

20 an electric generator coupled to and driven by the gas turbine engine rotary shaft, the electric generator having an electrical power output which, in combination with the fuel cell power output, provides electrical energy to drive the at least one electric motor; and

25 a power controller responsive to a control signal from the vehicle occupant to vary output of the at least one electric motor, the power controller regulating the fuel cell and the gas turbine operation to cause the fuel cell and the fuel cell exhaust gases to power the vehicle when the vehicle's power needs are generally below the maximum fuel cell power output and to provide hydrocarbon fuel to the combustor of the gas turbine to generate additional power as needed by the vehicle up to a maximum sustainable power, wherein the fuel cell is sized
30 relative to the vehicle and the gas turbine engine so that up to about 50% of the maximum sustainable power is supplied by the electric power output of the fuel cell.

2. The hybrid electric vehicle of claim 1, wherein the maximum fuel cell power output is no greater than about 25% of the maximum sustainable power level.

5 3. The hybrid electric vehicle of claim 1, wherein the maximum fuel cell power output is about 10% of the maximum sustainable power level.

4. The hybrid electric vehicle of claim 1, wherein the fuel cell is sized relative to the gas turbine engine and the vehicle so that, when the vehicle is operating at an average power level required by the vehicle during the Urban
10 Dynamometer Driving Schedule, over 50% of the vehicle power requirements are supplied by the electric power output of the fuel cell.

5. The hybrid electric vehicle of claim 4, wherein over 60% of the vehicle's power needs are supplied by the electric power output of the fuel cell when the vehicle is operating at the average power level occurring during the
15 Urban Dynamometer Driving Schedule.

6. The hybrid electric vehicle of claim 4, wherein approximately two-thirds of the vehicle's power needs are supplied by the electric power output of the fuel cell when the vehicle is operating at the average power level occurring during the Urban Dynamometer Driving Schedule.

20 7. The hybrid electric vehicle of claim 1, further including a reformer interposed between the source of hydrocarbon fuel and the fuel cell hydrocarbon fuel inlet, the reformer having an air input and partially oxidizing the hydrocarbon fuel in a fuel rich environment before introduction into the fuel cell.

8. The hybrid electric vehicle of claim 1, wherein the gas turbine engine includes an internal recuperator for transferring heat from the gas turbine engine exhaust gases to preheat compressed air supplied to the fuel cell compressed air inlet.

- 5 9. A power source for a hybrid electric vehicle for generating electric power in an amount up to a maximum sustainable power level from a supply of a hydrocarbon fuel and air, the power source comprising:
- an air compressor generating a supply of compressed air;
 - 10 a fuel cell receiving a first quantity of the fuel and a first portion of the supply of compressed air, the fuel cell generating a first electrical power output and a supply of fuel cell exhaust gas, the first electrical power output reaching a maximum fuel cell power output no greater than about 50% of the maximum sustainable power level;
 - 15 a combustor receiving at least one of the group consisting of the supply of fuel cell exhaust gas and a mixture of a second quantity of the fuel and a second portion of the supply of compressed air, the combustor generating heated combustion products;
 - a turbine receiving the heated combustion products, the turbine generating a rotary output;
 - 20 an electric generator driven by the rotary output of the turbine, the electric generator having an electrical power output which, in combination with the fuel cell power output, provides electrical energy to drive the at least one electric motor; and
 - 25 a power controller responsive to a demand signal representative of an instantaneous power requirement, wherein the power controller regulates the first supply of fuel and the second supply of fuel such that the combined first and electrical power outputs exceed the instantaneous power requirement, and wherein the power controller shuts off the second supply of fuel when the instantaneous power requirement falls below the maximum fuel cell power output.

10. The power source of claim 9, wherein the maximum fuel cell power output is no greater than about 25% of the maximum sustainable power level.
- 5 11. The power source of claim 9, wherein the maximum fuel cell power output is about 10% of the maximum sustainable power level.
12. The power source of claim 9, including a valve for controlling the second portion of the supply of compressed air supplied to the combustor.
- 10 13. The power source of claim 9, further including a reformer for partially oxidizing the first supply of fuel.
14. The power source of claim 9, further including a recuperator for preheating the first portion of the supply of compressed air using a supply of turbine exhaust gases.

15. A method of generating electrical energy in an amount up to a maximum sustainable power level from a supplied hydrocarbon fuel and air, the method comprising:

5 compressing air with a compressor to obtain a supply of compressed air;

converting, in a fuel cell, a first supply of a fuel and a first portion of the supply of compressed air into a first electrical power output and a supply of fuel cell exhaust gas, the first electrical power output reaching a maximum fuel cell power output no greater than about 50 % of the maximum sustainable power level;

10 generating heated combustion products from the combustion of the supply of fuel cell exhaust gas with a second portion of the supply of compressed air and a second supply of fuel;

15 generating a rotary output by directing the heated combustion products through a turbine;

driving the compressor and an electric generator with the rotary output, the electric generator generating a second electrical power output; and

20 controlling the first and second supplies of fuel responsive to a demand signal representative of an instantaneous power requirement, the second supply of fuel being cut off when the instantaneous power requirement falls below the maximum fuel cell power output.

16. The method of claim 15, wherein the maximum electrical power output of the fuel cell is no greater than about 25% of the maximum sustainable power level.

25 17. The method of claim 15, wherein the maximum electrical power output of the fuel cell is about 10% of the maximum sustainable power level.

30 18. The method of claim 14, further including controlling the second portion of the supply of compressed air to achieve a desired air-fuel ratio when generating the heated combustion products.

19. The method of claim 14, further including partially oxidizing the first supply of fuel in a fuel-rich environment.

20. The method of claim 15, further including preheating the first portion of the supply of compressed air before generating the heated
5 combustion products.

APS

search terms: hybrid vehicle, fuel cell, gas turbine

C. DOCUMENTS CONSIDERED TO BE RELEVANT

Category*	Citation of document, with indication, where appropriate, of the relevant passages	Relevant to claim No.
Y	US 5,678,647 (WOLFE et al) 21 October 1997, Figures 4-5.	1-7, 9-13, 15-19
Y	5,811,201 (SKOWRONSKI) 22 September 1998, Figure 1	1-6, 8-12, 14-18, 20
A	5,409,784 (BROMBERG et al) 25 April 1995, Figures 2 & 14	1-6, 9-12, 15-18
A	5,248,566 (KUMAR et al) 28 September 1993, Figures 2-3	1, 7, 9
A	5,532,573 (BROWN et al) 2 July 1996, Figures 1-2	7, 13, 19
A	5,762,156 (BATES et al) 9 June 1998, Figure 1, item 24	1, 9, 15

☐ Further documents are listed in the continuation of Box C.☐ See patent family annex.

* Special categories of cited documents:	*T* later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention
A document defining the general state of the art which is not considered to be of particular relevance	*X* document of particular relevance; the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone
E earlier document published on or after the international filing date	*Y* document of particular relevance; the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art
L document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)	*G* document member of the same patent family
O document referring to an oral disclosure, use, exhibition or other means	
P document published prior to the international filing date but later than the priority date claimed
